

Testing Plan Report

Please don't use my assignment for any in-class examples

Purpose: The purpose of this plan is to thoroughly test the different components and functionalities of our application, specifically the self-check in process. The test aims to identify any points of failure, anomalies, discomfort, or user issues in the overall working of the application. By doing so, I can identify areas of improvement and modifications, if needed, before I proceed with the finalizing of this prototype through coding and implementation.

Scope: I will be testing the entire self-check-in process within the web app, including the following features and task flows:

1. **QR code scanning functionality:** Assessing the ease and effectiveness of scanning QR codes upon entry to the urgent care center, ensuring seamless transition to the web app for self-check-in.
2. **Registration and input of personal details:** Evaluating the user experience during input of comprehensive personal information, including assessing form usability, data validation, and privacy considerations.
3. **Personalized time selection functionality:** Testing the ability of users to select preferred appointment times based on their availability, preferences, and urgency of medical needs, ensuring flexibility and convenience in scheduling.
4. **Appointment scheduling and doctor assignment:** Evaluating the process of scheduling appointments and assigning doctors, assessing clarity of available time slots, provider selection, and any potential challenges in rescheduling or canceling appointments.

5. **Navigation and Information Architecture:** Assessing the overall structure and organization of content within the web app, evaluating ease of navigation between different sections, clarity of labels, and hierarchy of information to ensure intuitive user interaction and efficient information retrieval.

Audience: I will be conducting usability testing with a diverse group of users comprising approximately 10 individuals. User group will include:

- ☐ Age range: 15-75+
- ☐ Gender: Male, Female
- ☐ Occupation: Students, Working professionals, and Retirees
- ☐ Ability-level: Different levels of technical proficiency, including both tech-savvy and less tech-savvy individuals. Individuals with different levels of understanding of medical terminology and procedures. We will include this diversity to ensure that the web app is accessible and usable by all age groups and a wide range of users who may visit an urgent care center.

Moderation: The test will be unmoderated, allowing users to interact with the prototype independently without guidance or observation from a moderator. This approach enables us to gather more natural and unbiased feedback on the usability of the web app, as users navigate through the tasks at their own pace and without external influence. This will help me identify the areas where they are stuck or find difficulty in navigating through, which will ultimately help me gain deeper insights to what needs to be changed and investigated.

Remote: The testing will be conducted both in-person and through video calls. Some users will participate in the testing sessions in person, allowing for direct observation of their interactions with the prototype. Additionally, other users will participate remotely via video calls, providing flexibility for testers who may not be able to attend in person. This approach enables us to accommodate a diverse range of users while still allowing for real-time observation and interaction.

Metrics:

- **Task Success Rate:** Quantitative measure of the percentage of tasks completed successfully by users. This metric measures the effectiveness of the web app in self check-in.
- **Time to Completion:** Quantitative measure of the time taken by users to complete each task. This metric provides insights into the efficiency of the web app.
- **Error Rate:** Quantitative measure of the frequency of errors encountered by users during the self-check-in process. This metric helps identify usability issues and areas for improvement in error handling and prevention.
- **Satisfaction Scale:** Qualitative measure of overall user satisfaction and perceived usability of the web app. This metric provides insights into users' subjective experiences and satisfaction levels.

Unknowns:

- How intuitive is the QR code scanning process for users of varying technical proficiency?
- Will users encounter any difficulties or confusion while inputting their medical information, and how can we streamline this process?

- Are there any privacy or security concerns raised by users during the registration and input of personal details?
- After inputting all the information, is an appropriate doctor assigned to that individual?
- How do users perceive the estimated appointment time provided by the web app, and is it accurate enough to meet their expectations?
- What additional features or functionalities would users like to see in the self-check-in web app to enhance their experience and convenience?
